# Abstract

This report details the implementation of regression models to predict bike-sharing demand. We implemented Linear Regression, Polynomial Regression (degrees 2, 3, 4), and a Quadratic Model with interaction terms. Models were evaluated on a strictly held-out test set. The **Quadratic Model with Interactions** achieved the lowest MSE, demonstrating that demand is best explained by the complex interplay between features rather than individual factors alone.

## 1 Problem Statement and Data

### 1.1 Objective

The goal is to predict the hourly bike rental count ('count') based on environmental settings (temperature, humidity, windspeed) and seasonal factors.

### 1.2 Dataset & Preprocessing

The dataset contains timestamped records. We performed the following preprocessing steps (see Appendix A.1 for code):

- **Feature Engineering:** Extracted 'hour', 'dayofweek', 'month', and 'year'.
- **Encoding:** Categorical variables were One-Hot Encoded. Numeric variables were Standard Scaled.
- **Splitting:** A strict 80-20 Train-Test split was used to prevent data leakage.

## 2 Methodology: Model Selection

We compared three types of models to analyze the bias-variance trade-off (see Appendix A.2 for definitions):

### 2.1 1. Linear Regression (Baseline)

Assumes a direct linear relationship ( $y = w^T x + b$ ). This model serves as a baseline to detect underfitting.

### 2.2 2. Polynomial Regression (Degrees 2, 3, 4)

Introduces non-linearity ( $x^2, x^3 \dots$ ) but explicitly excludes interaction terms. This tests if individual feature curvature (e.g., non-linear temperature effects) sufficiently explains the variance.

### 2.3 3. Quadratic Model with Interactions

A degree-2 polynomial that includes interaction terms ( $x_i \cdot x_j$ ). We hypothesize that features are interdependent (e.g., the effect of 'humidity' depends on 'temperature').

## 3 Results and Analysis

### 3.1 Performance Evaluation

The models were evaluated strictly on the test set. The full results are provided in Table 1 (Appendix B).

- **Linear Regression:**  $\text{MSE} \approx 10027$ ,  $R^2 \approx 0.696$
- **Polynomial (Deg 4):**  $\text{MSE} \approx 9806$ ,  $R^2 \approx 0.703$
- **Quadratic Interaction:**  $\text{MSE} \approx \mathbf{9755}$ ,  $R^2 \approx \mathbf{0.704}$

## 3.2 Discussion: Which model is better and why?

Based on the experimental results, the **Quadratic Model with Interactions** is the superior model.

### 3.2.1 1. The Role of Interactions

The interaction model achieved the lowest MSE (9755.92). Even though the Degree 4 Polynomial is mathematically more complex in terms of curvature, it failed to beat the Degree 2 Interaction model.

- **Reasoning:** A pure polynomial model assumes features act independently. However, in reality, a rainy day at 5 PM (rush hour) causes a much larger drop in bikes than a rainy day at 3 AM. This conditional relationship is captured by the interaction term  $x_{hour} \cdot x_{weather}$ , which is absent in pure polynomial models.

### 3.2.2 2. Bias-Variance Trade-off

The Linear model performed worst, proving the data is non-linear (High Bias). While increasing the polynomial degree ( $2 \rightarrow 4$ ) improved accuracy, the gains diminished. The Interaction model utilized "smarter" complexity (cross-features) rather than just "higher" complexity (powers), allowing it to generalize better without the overfitting risks associated with high-degree polynomials.

## 4 Conclusion

The analysis confirms that bike-sharing demand is driven by complex, interdependent factors. The Quadratic Interaction model strikes the optimal balance, leveraging cross-feature dependencies to provide the most accurate predictions.

## A Appendix: Implementation Code

### A.1 Preprocessing Code

```
10 df["datetime"] = pd.to_datetime(df["datetime"])
11 df["hour"] = df["datetime"].dt.hour
12 df["dayofweek"] = df["datetime"].dt.dayofweek
13 df["month"] = df["datetime"].dt.month
14 df["year"] = df["datetime"].dt.year.map({2011: 0, 2012: 1})
15
16 y = df["count"]
17
18 numeric_features = ["temp", "atemp", "humidity", "windspeed"]
19 categorical_features = [
20     "season", "holiday", "workingday", "weather",
21     "hour", "dayofweek", "month", "year"
22 ]
23
24 X = df[numeric_features + categorical_features]
25
26 X_train, X_test, y_train, y_test = train_test_split(
27     X, y, test_size=0.2, random_state=42
28 )
```

### A.2 Model Definition Code

```
33 # Linear Model
34 models["linear"] = Pipeline([
35     ("preprocess", preprocess_linear),
36     ("regressor", LinearRegression())
37 ])
38
39 # Polynomial Models without interaction terms
40 for d in [2, 3, 4]:
41     num_poly = Pipeline([
42         ("scaler", StandardScaler()),
43         ("powers", PowerFeatures(degree=d))
44     ])
45
46     preprocess_poly = ColumnTransformer([
47         ("num", num_poly, numeric_features),
48         ("cat", cat, categorical_features)
49     ])
50
51     models[f"poly_deg_{d}_no_inter"] = Pipeline([
52         ("preprocess", preprocess_poly),
53         ("regressor", LinearRegression())
54     ])
55
56 # Quadratic Model with interaction terms
57 num_quad = Pipeline([
58     ("scaler", StandardScaler()),
59     ("poly", PolynomialFeatures(degree=2, include_bias=False))
60 ])
61
62 preprocess_quad = ColumnTransformer([
63     ("num", num_quad, numeric_features),
64     ("cat", cat, categorical_features)
65 ])
66
67 models["quadratic_with_interactions"] = Pipeline([
68     ("preprocess", preprocess_quad),
69     ("regressor", LinearRegression())
70 ])
```

### A.3 Training and Evaluation Code

```
7     for name, model in models.items():
8         print(f"Training {name}...")
9         model.fit(x_train, y_train)
10
11         preds = model.predict(X_test)
12         mse = mean_squared_error(y_test, preds)
13         r2 = r2_score(y_test, preds)
14
15         results.append({
16             "model": name,
17             "test_MSE": mse,
18             "test_R2": r2
19         })
```

## B Appendix: Results Table

Model Configuration	Test MSE	Test $R^2$ Score
Linear Regression	10027.06	0.6962
